Abstract: Hardware Transaction Memory (HTM) opens a new way to scaling multi-core software. Its main target is to achieve high performance on multi-core systems, and at the same time simplify concurrency control and guarantee correctness. This paper presents the redesign of an existing concurrent hash table using several HTM-based synchronization mechanisms. As compared with a fine-grained lock implementation, HTM-based locking scales well on our testing platform, and its performance is higher when running large-scale workloads. In addition, HTM-based global locking consumes much less memory. In summary, several observations are made in this paper with detailed experimental analysis, which would have important implications for future research of concurrent data structures and HTM. © 2017 Springer Science+Business Media, LLC

Main heading: Concurrency control

Controlled terms: Data structures - Hardware - Locks (fasteners) - Synchronization

Uncontrolled terms: Concurrent data structures - Experimental analysis - Hardware transactional memory - Hash table - Implications for futures - Multi-core systems - Synchronization mechanisms - Transaction memory
